Assume you are a Chancellor Of Private University and you are having less results in Btech DataScience.You are hiring a DataAnalyst who can work on the raw data of students and give you useful insights.The DataAnalyst has now start the process with Data Collection, Data Cleaning, Data Encoding & Data Visualization Such that the insights given by him are useful for your university.

DATA COLLECTION

The dataset utilized in this analysis is a mock dataset specifically created for the purpose of illustrating the essential procedures involved in data analysis. It serves as a practical tool to showcase the various steps and methodologies that should be employed when working with an authentic dataset to extract the desired insights. While the data within this mock dataset is synthetic, the analysis techniques applied herein mirror those employed in real-world scenarios, enabling users to acquire a comprehensive understanding of the data analysis process. By utilizing this simulated dataset, users can familiarize themselves with the methodologies and gain the necessary proficiency to effectively tackle data analysis tasks using genuine datasets.

[1]:
```
import pandas as pd
```

[6]:
```
# Load the dataset
df = pd.read_excel('DPFE Capstone Project Dataset.xlsx')
df.head(10)
```

```

1.0.1 - INSIGHTS -

- The analysis of the final score distribution reveals that the majority of students' scores fall within the range of 80 to 90. However, to achieve a satisfactory level of performance, there is a need to push the scores towards the 90s. This indicates a potential area of improvement and suggests implementing strategies to enhance student performance and raise the overall score distribution to meet the desired satisfactory threshold.
- The analysis of the final exam scores by gender indicates that females tend to have higher performance compared to males. This insight suggests that more attention and support should be directed towards male students to bridge the performance gap and help them achieve comparable levels of success. Implementing targeted interventions and tailored support systems can potentially enhance the performance of male students and ensure equitable outcomes across genders.
- The analysis based on programming languages reveals that there is no significant difference in performance between R and Python users, although Python users have a slight edge. This insight suggests that both R and Python are equally effective languages for students in terms of achieving academic success. However, the slight advantage observed for Python

may indicate its popularity and versatility in the field of data science, encouraging students to consider it as a preferred language for their studies.

- The analysis of attendance and final exam scores demonstrates a generally positive correlation, indicating that higher attendance is associated with better performance on the final exams. However, there are a few outliers where students with high attendance did not achieve expected scores. These outliers may be influenced by other factors, such as individual learning styles or external circumstances, highlighting the need for a holistic approach to student support and identifying potential areas for targeted interventions.
